PROJECT REPORT

Name: Jainish Jain

Registration Number: 25BCE11323

Subject Code: Fundamentals in AI and ML (CSA2001)

Branch: Computer Science & Engineering CORE

Date: March 30 , 2026

Dice Simulator with AI-Based Prediction System

INTRODUCTION

This project presents a graphical dice simulator built using Python and the CustomTkinter library. The system not only simulates the rolling of a standard six-faced dice but also integrates a basic artificial intelligence mechanism to analyze previous results and provide predictions. The application is designed to be interactive, user-friendly, and informative. It demonstrates how randomness and statistical analysis can be combined within a modern graphical interface. The project also highlights fundamental programming concepts such as event handling, data structures, and modular design.

MOTIVATION OF THE PROJECT

The primary motivation behind this project is to bridge the gap between theoretical concepts and practical implementation. Students often learn about probability and randomness in theory but lack opportunities to visualize and apply these concepts. This project provides a platform to explore these ideas interactively. Additionally, the project introduces GUI development using CustomTkinter, which enhances the

learning experience. The aim is to create a system that is simple yet meaningful, encouraging further exploration into artificial intelligence and predictive systems.

PROBLEM STATEMENT

Most traditional dice simulators simply generate random values without providing any form of analysis or feedback. Users are unable to observe patterns or understand the probability distribution of outcomes. This lack of analytical insight limits the educational and practical value of such systems. Therefore, the problem addressed in this project is the absence of data tracking and predictive functionality in basic simulators. The goal is to design a system that not only generates random results but also records, analyzes, and predicts outcomes effectively.

OBJECTIVE OF THE PROJECT

The main objective of this project is to design and develop a dice simulation system with enhanced analytical capabilities. The system aims to simulate dice rolls using random number generation and provide a graphical interface for better user interaction. Another objective is to implement a simple prediction model based on historical data. Additionally, the project focuses on displaying statistical information such as frequency and probability. Overall, the objective is to create an educational tool that demonstrates the relationship between randomness and prediction.

EXISTING METHODS

Existing methods for dice simulation include command-line programs, simple graphical applications, and online random number generators. These systems typically generate random numbers within a specified range and display the result. While they are efficient and easy to implement, they lack advanced features such as data storage, analysis, and prediction. Some web-based tools provide visual representations, but they still do not offer meaningful insights into the results. Therefore, existing methods are limited in functionality and do not fully utilize the potential of data analysis.

PROS AND CONS OF THE STATED METHODS

The existing methods have several advantages, including simplicity, speed, and low resource consumption. They are easy to implement and suitable for basic applications. However, they also have significant limitations. They do not store previous results, making it impossible to analyze trends or patterns. Additionally, they lack predictive capabilities, which reduces their usefulness in educational

contexts. The absence of a graphical interface in many cases also limits user engagement. These drawbacks highlight the need for a more advanced and interactive solution.

HARDWARE AND SOFTWARE REQUIREMENTS

The hardware requirements for this project are minimal, making it accessible to most users. A standard computer with at least 4 GB of RAM and a basic processor is sufficient to run the application smoothly. On the software side, the project requires Python 3.x as the programming language. The CustomTkinter library is used for building the graphical interface, while built-in modules such as random and collections are used for generating values and analyzing data. The system is compatible with major operating systems including Windows, Linux, and macOS.

METHODOLOGY AND GOAL

The methodology of this project involves a step-by-step approach to simulate, store, analyze, and display data. Initially, a random number between 1 and 6 is generated to simulate a dice roll. The result is stored in a history list, which is then analyzed using the Counter class to determine frequency distribution. Based on this analysis, the system predicts the most likely outcome. The goal is to create a system that is both interactive and informative, allowing users to understand the behavior of random processes through visualization and analysis.

FUNCTIONAL MODULES DESIGN AND ANALYSIS

The system is divided into several functional modules to ensure modularity and ease of maintenance. The dice rolling module handles random number generation. The AI prediction module stores historical data and calculates predictions based on frequency. The statistics module computes probabilities and displays them in a readable format. The GUI module manages user interaction, including buttons, labels, and display areas. Each module is designed to perform a specific task, ensuring that the system remains organized and efficient.

ALGORITHM DEVELOPMENT

The algorithm begins with initializing an empty list to store dice roll history. When the user triggers a roll, a random number between 1 and 6 is generated. This value is displayed and added to the history. The system then uses the Counter class to calculate the frequency of each number. The most frequently occurring number is selected as the prediction. Probabilities are calculated by dividing the frequency by

the total number of rolls. The results are displayed to the user, and the process repeats until the application is closed.

SOFTWARE ARCHITECTURAL DIAGRAM

The architecture of the system follows a simple layered approach. The user interacts with the graphical interface, which sends input to the application logic. The logic layer processes the input and communicates with the AI module, which performs analysis and prediction. The results are then passed back to the interface for display. This separation of concerns ensures that each component operates independently while contributing to the overall functionality. The design improves maintainability and scalability of the application.

CODING

The implementation of the project is carried out using Python due to its simplicity and extensive library support. The CustomTkinter library is used to create a modern and responsive graphical interface. The random module is used to simulate dice rolls, while the collections module provides tools for data analysis. The code is organized into classes and functions to promote reusability and clarity. Proper coding practices such as naming conventions and modular design are followed to ensure readability and maintainability.

OUTPUT

The output of the system is displayed through a graphical interface. When the user rolls the dice, the result is shown along with a visual representation using ASCII characters. The AI prediction is displayed based on historical data. Additionally, the system provides a detailed breakdown of frequency and probability for each possible outcome. This output allows users to observe patterns and understand the distribution of results. The interface is designed to be clear and intuitive, enhancing the overall user experience.

KEY IMPLEMENTATIONS OUTLINE OF THE SYSTEM

The key implementations of the system include random number generation, data storage, statistical analysis, and graphical display. The system maintains a history of all dice rolls and uses this data to compute frequency and probability. The prediction mechanism is based on identifying the most frequent outcome. The graphical interface integrates all components, allowing users to interact with the

system easily. These implementations work together to create a comprehensive and functional application.

SIGNIFICANT PROJECT OUTCOMES

The project successfully demonstrates the integration of simulation, data analysis, and graphical interface design. It provides an interactive platform for understanding randomness and probability. The addition of a prediction system enhances the functionality and educational value of the application. Users can observe how outcomes change over time and how predictions are influenced by historical data. The project also highlights the importance of modular design and clean coding practices in software development.

TESTING AND REFINEMENT

The system is tested by performing multiple dice rolls and verifying the accuracy of the results. The frequency and probability calculations are checked to ensure correctness. The graphical interface is tested for responsiveness and usability. Any errors or inconsistencies are identified and corrected during the refinement process. The testing phase ensures that the application performs reliably under different conditions. Continuous improvement is carried out to enhance performance and user experience.

PROJECT APPLICABILITY ON REAL-WORLD APPLICATIONS

Although the project is simple, it demonstrates concepts that are widely used in real-world applications. Data analysis and prediction are fundamental aspects of many systems, including finance, gaming, and machine learning. The ability to track historical data and make predictions based on patterns is essential in decision-making processes. This project serves as a foundation for understanding these concepts and can be extended to more complex applications in various domains.

CONTRIBUTION/ FINDINGS OF THE PROJECT

The project contributes to understanding how basic statistical methods can be applied in software applications. It demonstrates that even simple systems can provide valuable insights when combined with data analysis. One of the key findings is that prediction based on frequency can give an approximation of future outcomes, although it is not always accurate due to the nature of randomness. The project also highlights the importance of user interface design in making applications more engaging and informative.

LIMITATION/CONSTRAINTS OF THE SYSTEM

The system has certain limitations that affect its accuracy and scope. The prediction mechanism is based solely on frequency, which does not account for true randomness. As a result, the predictions may not always be reliable. The application is also limited to a six-faced dice and does not support customization. Additionally, the system does not include advanced visualization tools such as graphs or charts. These constraints highlight areas for improvement and further development.

CONCLUSIONS

The Dice Simulator with AI-Based Prediction System achieves its objective of combining simulation with basic analytical features. It provides an interactive and educational platform for understanding randomness and probability. The integration of a graphical interface enhances usability and user engagement. While the prediction system is simple, it effectively demonstrates the concept of data-driven decision-making. Overall, the project serves as a valuable learning experience and a foundation for more advanced applications.

FUTURE ENHANCEMENTS

There are several opportunities for improving the system in the future. Advanced prediction algorithms such as machine learning models can be implemented to enhance accuracy. Graphical visualization tools such as charts and graphs can be added to represent data more effectively. The interface can be further improved with animations and better design elements. Additional features such as multiplayer functionality or online integration can also be explored. These enhancements would significantly increase the scope and usability of the application.

REFERENCES

The project is developed using information from various reliable sources. Python official documentation is used for understanding core programming concepts. The CustomTkinter documentation provides guidance for building the graphical interface. Additional references include online tutorials and educational resources on probability and data analysis. These sources ensure that the project is based on accurate and up-to-date information.
